## 1 Introduction

In this paper we demonstrate the simulation of stock prices using a geometric Brownian motion.

## 2 Simulation model

A stochastic process  $S_t$  is said to follow a Geometric Brownian Motion (GBM) if it satisfies the following stochastic differential equation (SDE):

$$dS_t = \mu S_t dt + \sigma S_t dW_t$$

where  $W_t$  is a Wiener process or Brownian motion, and  $\mu$  (the percentage drift) and  $\sigma$  (the percentage volatility) are constants.

For an arbitrary initial value  $S_0$  the above SDE has the analytic solution:

$$S_t = S_0 \exp \left( \left( \mu - \frac{\sigma^2}{2} \right) t + \sigma W_t \right)$$

## 3 Numerical example

In this section we simulate the price evolution of the share of two fictitious companies—Tyrell Corporation and Cyberdyne Systems—with the parameters described in Table 1. As we can see in Figure 1 increasing the  $\sigma$  parameter

Table 1: Parameters for the simulation

	$\mu$	$\sigma$
<b>Tyrell</b>	0.02	0.2
<b>Cyberdyne</b>	0.03	0.25

produces the expected effect of lower density in the center of the distribution and higher density towards the tails.
